Description

This invention relates to a novel condensed pyrimidine derivative useful as an anti-tumor agent, its production and use.

Folic acid and its related compounds are carriers of a C1 unit in a living body, derived from formic acid or formaldehyde, acting as a coenzyme in various enzymatic reactions such as those in biosynthesis of nucleic acid, in metabolism of amino acids and peptides and in generation of methane. Particularly for metabolism and transition reaction of C1 units in biosynthesis of nucleic acid, i.e. the purine synthetic pathway and the thymidine synthetic pathway, folic acid and its related compounds are essential. In order for folic acid to demonstrate its biological activities, normally, it is required to undergo two steps of reduction to be transformed into its active coenzyme form. As a drug substance which binds strongly to the enzyme (dihydrofolate reductase : DHFR) governing the second reduction step to thereby inhibit the reduction of dihydrofolate to tetrahydrofolate, there are known amethopterin (methotrexate: MTX) and its analogous compounds. These drugs, that act to exert damage to DNA synthesis, eventually bringing about cell death, have been developed as an antitumor agent and occupy a clinically important position as therapeutic agent of, mainly, leukemia. Furthermore, with remarkable developments of research work in the field of biochemistry, especially in the field of folic acid and relating compounds for the therapy of cancers, reports have been made of a novel DHFR inhibitor, namely a 10-deazaaminopterin-based antitumor agent (10-ethyl-10-deazaaminopterin: 10-EDAM) [NCI Monograph, 5, 127 (1987)] or an aminopteroyl type ornithine derivative, namely an N(α)-(4-amino-4-deoxypteroyl)-N(δ)-hemiphthaloyl-L-ornithine: PT523 [Japanese Publish unexamined Patent Application No. 502095/1990], and an antagonism inhibiting agent aiming at an enzyme different from DHFR, namely a 5-deazatetrahydro folic acid-based antitumor agent, which can act principally through a mechanism to inhibit glycinamideribonucleotide transformylase, namely 5,10-dideaza-5,6,7,8-tetrahydro folic acid: DDATHF [Journal of Medicinal Chemistry, 28, 914(1985)] or a quinazoline-based antitumor agent, which can work principally through a mechanism to inhibit thymidylate synthetase (2-desamino-2-methyl-10-propargyl-5,8-dideazafolate: DMPDDF) [British Journal of Cancer, 58, 241 (1988)]. All of these compounds are, however, within the category of heterocyclic compounds having a basic skeleton of a condensed ring of 6-membered rings (6-6 condensed ring). On the other hand, it was also reported that the folic acid antagonistic agents having the pyrrolo[2,3-d] pyrimidine ring as the basic skeleton which is a condensed ring from a 6-membered ring and a 5-membered ring has excellent antitumor activity, as well. However, there has been described that it is essential for the above-mentioned pyrrolo[2,3-d]pyrimidine derivatives to have glutamic acid mainly at the terminal side chain [USP4,997,838, EP-A-400,562, EP-A-402,903, EP-A-418,924, EP-A-431,953, EP-A-434,426, EP-A-438,261 and USP4,996,206].

What is now specifically desired in the field of cancer therapy is the creation of drugs which have toxicities highly specific to cancer cells based on the action mechanism having excellent therapeutic effects. The MTX whose principal action mechanism consists in inhibition of dihydrofolate reductase is clinically used widely, though the therapeutic effect is still unsatisfactory because it has relatively strong toxicity with little effect on solid cancer. Further, acquired resistance against MTX has now been taken up as a great problem. As the resistance mechanism against MTX, there are counted, for example, rise of DHFR level, lowering of cell membrane capability of carrying drugs and lowering of the level of folypolyglutamate synthetase (FPGS). By overcoming at least one of these resistance factors, development of drugs showing excellent therapeutic effect against MTX-resistant cancers has been expected.

This invention provides a novel condensed heterocyclic compounds which have not only 6-5 condensed ring as the basic skeleton but also, at the terminal side-chain, no two coexisting carboxyl groups derived from glutamic acid inhibit not less than one of the enzymatic reactions involving folic acid, exhibit highly selective toxicity against various tumors (especially human lung cancer cells) and also produce excellent antitumor effect which also overcome MTX-resistance.

This inventors of present invention explored compounds which could be of use as medicament for inhibiting tumor and particularly compounds of value for inhibiting cell-proliferation and succeeded in the creation of a condensed pyrimidine derivative of the formula (I):

wherein the ring A stands for an optionally hydrogenated 5-membered ring optionally having substituents; B stands for an optionally substituted divalent 5- or 6-membered homo- or hetero-cyclic group; X stands for an amino group,

In the above formulae, the compounds of this invention can exist as an equilibrium mixture with their tautomeric isomers. Illustrated below are the partial structural formulae capable of undergoing tautomerism, with the equilibria among them being shown as well.

Throughout this specification, for the purpose of convenience of expression, the amino, hydroxyl and mercapto forms are to be described, with the corresponding designations being adopted, and in either case, their tautomers or the imino, oxo and thioxo forms are understood to be included in the scope of this invention.

Below described is the process for producing the compounds (I) of this invention or their salts.

The compound (I) or its salt can be obtained by acylating a compound (III) or its salt with a compound (II), its salt or reactive derivative at the carboxyl group. The above-mentioned acylating means includes, for example, a procedure of acylating the compound (III) or its salt with the compound (II), its salt or reactive derivative. It is advantageous to

conduct this reaction in the presence of, for example, carbodiimides, diphenylphosphoric azide or diethyl cyanophosphate. The amount of the compound (III) or its salt to be used ranges usually from about 1 to 20 mole equivalents relative to the compound (II) or its salt, reactive derivative at the carboxyl group, preferably about 1 to 5 mole equivalents. The amount of carbodiimides, diphenylphosphoric azide and diethyl cyanophosphate to be used is usually in the range from about 1 to 25 mole equivalents, preferably about 1 to 5 mole equivalents relative to the compound (II) or its salt, reactive derivative at the carboxyl group.

As the carbodiimides, dicyclohexylcarbodiimide is desirable from the stand of practical use, while any other carbodiimides, for example, diphenylcarbodiimide, di-o-tolylcarbodiimide, di-p-tolylcarbodiimide, di-tert-butylcarbodiimide, 1-cyclohexyl-3-(2-morpholinoethyl)carbodiimide, 1-cyclohexyl-3-(4-diethylaminocyclohexyl)carbodiimide, 1-ethyl-3-(2-diethylaminopropyl)carbodiimide and 1-ethyl-3-(3-diethylaminopropyl)carbodiimide may be used.

This acylation reaction may be conducted in the presence of an adequate solvent, as exemplified by water, alcohols (e.g. methanol and ethanol), ethers (e.g. dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme and diglyme), nitriles (e.g. acetonitrile), esters (e.g. ethyl acetate), halogenated hydrocarbons (e.g. dichloromethane, chloroform and carbon tetrachloride), aromatic hydrocarbons (e.g. benzene, toluene and xylene), acetone, nitromethane, pyridine, dimethyl sulfoxide, dimethylformamide, hexamethylphosphoramide, sulfolane or suitable mixtures of them. This reaction is conducted at a pH usually in the region of about 2 to 14, preferably about 6 to 9, at temperatures usually ranging from about -10°C to the boiling point (up to about 100°C) of the solvent then used, preferably about 0 to 50°C, usually for about 1 to 100 hours. The pH of the reaction solution is, upon necessity, adequately adjusted with, for example, acids (e.g. hydrochloric acid, sulfuric acid, phosphoric acid, nitric acid and acetic acid), bases (e.g. sodium methylate, sodium ethylate, sodium hydroxide, potassium hydroxide, lithium hydroxide, sodium carbonate, potassium carbonate, barium carbonate, calcium carbonate, sodium hydrogencarbonate, trimethylamine, triethylamine, triethanolamine and pyridine) or buffers (e.g. phosphate buffer, borate buffer and acetate buffer). This reaction can be allowed to proceed more advantageously by the aid of a catalyst capable of accelerating acylation. As such catalysts, use is made of, for example, base catalysts and acid catalysts. Examples of the base catalysts include tertiary amines (e.g. aliphatic tertiary amines such as triethylamine; aromatic tertiary amines such as pyridine, α -, β - or γ -picoline, 2,6-lutidine, 4-dimethylaminopyridine, 4-(1-pyrroldinyl)pyridine, dimethylaniline and diethylaniline), while examples of the acid catalysts include Lewis acids [e.g. anhydrous zinc chloride, anhydrous aluminum chloride (AlCl_3), anhydrous ferric chloride, titanium tetrachloride (TiCl_4), tin tetrachloride (SnCl_4), antimony pentachloride, cobalt chloride, cupric chloride and boron trifluoride etherate]. Among the above-exemplified catalysts, 4-dimethylaminopyridine or 4-(1-pyrroldinyl)pyridine is preferably employed in many cases. The amount of the catalysts to be employed ranges usually from about 0.1 to 10 mole equivalents relative to the compound (II) or its salt, reactive derivative at the carboxyl group, preferably from about 0.1 to 1 mole equivalent. Examples of the reactive derivative of the compound (II) in regard to the carboxyl group include derivative of the compound (II), such as its acid halide (e.g. fluoride, chloride, bromide and iodide), its acid anhydride (e.g. iodoacetic anhydride and isobutyric anhydride), its mixed acid anhydride with lower monoalkyl carbonate (e.g. monomethyl carbonate, monoethyl carbonate, monopropyl carbonate, monoisopropyl carbonate, monobutyl carbonate, monoisobutyl carbonate, mono-sec-butyl carbonate and mono-tert-butyl carbonate), its active esters (e.g. cyanomethyl ester, ethoxycarbonylmethyl ester, methoxymethyl ester, phenyl ester, o-nitrophenyl ester, p-nitrophenyl ester, p-carbomethoxyphenyl ester, p-cyanophenyl ester, phenylthio ester and succinimide ester), its acid azide, its mixed acid anhydride with diester of phosphoric acid (e.g. dimethyl phosphate, diethyl phosphate, dibenzyl phosphate and diphenyl phosphate) and its mixed anhydrides with diester of phosphorous acid (e.g. dimethyl phosphite, diethyl phosphite, dibenzyl phosphite and diphenyl phosphite). In the acylation process using these reactive derivatives, the reaction conditions such as the solvent, catalyst, reaction temperatures and reaction time are substantially the same as those described previously referring to the acylation conducted in the presence of carbodiimide and so on.

Incidentally, in the case of producing the compound or a salt thereof which has a hydroxyl group, amino group, mercapto group or carboxyl group in the compound (I) or its salt, the object compound (I) or its salt can be produced by protecting the hydroxyl group, amino group, mercapto group or carboxyl group of the starting compound with a per se known protective group according to a per se known method (e.g. J. F. W. McOmie, *Protective Groups in Organic Chemistry*, Plenum Press, London and New York (1973)) followed by subjecting the reaction product to a per se known deprotection reaction.

Described in the following is the procedure of producing the starting compound (II), its salt or reactive derivative at the carboxyl group.

Among them, acid halide is preferable.

The compound (II), its salt or reactive derivative at the carboxyl group can be produced by, for example, the following reaction steps.

In the above formulae, the ring A, B, D, Y and Z are of the same meaning as defined above, and examples of R³ at the optionally esterified carboxyl group represented by COOR³ include hydrogen atom, or a C₁₋₅ alkyl group, optionally substituted benzyl group or an optionally substituted phenyl group specifically described referring to COOR²; D and E are group being capable of combining with each other to form Z. In the above reaction steps, the covalent bond can be allowed to form between D and E to thereby produce a straight-chain divalent aliphatic group having five or less chain-composing atoms optionally bonded through a hetero-atom at the site of chain. Referring to the synthetic method which permits formation of the covalent bond between the compound (V) or its salt and the compound (VI) or its salt, wherein Z is an optionally substituted divalent aliphatic group having five or less straight-chain atoms, the compound (V) or its salt and the compound (VI) or its salt can be subjected to the so-called reaction causing carbon-carbon bond, followed by subjecting the resultant to reduction, when necessary, to thereby produce the compound (V) or its salt, in case, for example, where D is

or in the case of vice versa $D=E'$ and $E=D'$.

In the above formulae, a , b , m , n ($= a+b$) and $m+n$ each denotes an integer in the range of 0 to 3; G stands for phenyl, butyl or cyclohexyl; M stands for ethyl or phenyl; R^5 , R^6 and R^7 independently stand for a bond, a hydrogen atom, the divalent lower hydrocarbon group represented by Z^1 and Z^2 described specifically, or the lower hydrocarbon group represented by R^4 , and they may be different from one another in repeating units m and n .

In the case of Z being a group composed of $Z=Z^1-Z^2-Z^3$, in the case of, for example,

or in the case of vice versa $D=E$ and $E=D'$, the so-called alkylation reaction is employed, and in the case of, for example, where D is

or in the case of vice versa $D=E^2$, $E=D^2$, so-called amine exchange reaction (glamine decomposition reaction) is advantageously employed, and in cases where D is

or in the case of vice versa $D=E^3$ and $E=D^3$, a Schiff base or enamine is allowed to form, followed by reduction, when necessary, or subjecting directly to a reductive alkylation reaction.

In the above formulae, m , n , $m+n$, R^4 , R^5 , R^6 , R^7 and Z^2 are of the same meaning as defined hereinbefore; L stands for a leaving group; and R^8 and R^9 independently stand for a hydrogen atom or a hydrocarbon group. Below given is the detailed description of the first step:

For the condensation reaction through the formation of carbon-carbon bonding, is employable according to a known reaction (e.g. aldol reaction, Reformatsky reaction or Wittig reaction), and, as the reduction reaction, catalytic reduction or hydride reduction is usually employed advantageously. In the case of employing aldol reaction for the condensation reaction, as the base catalyst, use is made of, for example, a metal hydroxide such as sodium hydroxide, potassium hydroxide, lithium hydroxide or barium hydroxide; a metal alkoxide such as sodium methoxide, sodium ethoxide or potassium tert-butoxide; a metal amide such as sodium amide or lithium diisopropylamide; a metal hydride such as sodium hydride or potassium hydride; an organometallic compound such as phenyllithium or butyllithium; and an amine such as triethylamine, pyridine, alpha-, beta- or gamma-picoline, 2,6-lutidine, 4-dimethylaminopyridine, 4-(1-pyrrolidinyl)pyridine, dimethylaniline or diethylaniline; while as the acid catalyst, use is made of, for example, a mineral acid such as hydrochloric acid, sulfuric acid, nitric acid, phosphoric acid or boric acid; and an organic acid such as oxalic acid, tartaric acid, acetic acid, trifluoroacetic acid, methanesulfonic acid, benzenesulfonic acid, p-toluenesulfonic acid or camphorsulfonic acid. Alternatively, the condensation can be conducted by, in accordance with a known method [Ei-Ichi Negishi, Organometallic in Organic Synthesis Vol. 1, John Wiley & Sons, New York, Chichester, Brisbane, Tronto (1980)], deriving a silylenol ether compound from ketone, which is subjected to condensation with aldehyde or its equivalent in the presence of a Lewis acid [e.g. anhydrous zinc chloride, anhydrous aluminum chloride (AlCl₃), anhydrous ferric chloride, titanium tetrachloride (TiCl₄), tin tetrachloride (SnCl₄), antimony pentachloride, cobalt chloride, cupric chloride or boron trifluoride etherate], fluorine anion (e.g. tetrabutyl ammonium fluoride) or trityl perchloride, or by processing the ketone compound with a metal triflate [e.g. dialkyl boron triflate or tin(II) triflate] in the presence of an amine [e.g. triethylamine, pyridine, alpha-, beta- or gamma-picoline, 2,6-lutidine, 4-dimethylaminopyridine, 4-(1-pyrrolidinyl)pyridine, dimethylaniline or diethylaniline] to convert into the enolate, then by subjecting the enolate to condensation with aldehyde or its equivalent. The condensation reaction can be carried out in an appropriate solvent at temperatures ranging from -100°C to the boiling point of the solvent then employed, preferably -78 to 100°C, for a period ranging from one minute to three days. Examples of the reaction solvent include water, liquid ammonia, alcohol (e.g. methanol, ethanol, propanol, iso-propanol, butyl alcohol, sec-butyl alcohol, tert-butyl alcohol, ethylene glycol, methoxyethanol or ethoxyethanol), ether (e.g. dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme or diglyme), halogenated hydrocarbon (e.g. dichloromethane, chloroform or carbon tetrachloride), aliphatic hydrocarbon (e.g. pentane, hexane or heptane), aromatic hydrocarbon (e.g. benzene, toluene or xylene), acetonitrile, nitromethane, dimethylformamide, dimethyl sulfoxide, hexamethylphosphoramide, sulfolane or a suitable mixture of them. In the case of resorting to Wittig reaction for the condensation, reagents to be employed are exemplified by a metal hydroxide such as sodium hydroxide, potassium hydroxide, lithium hydroxide or barium hydroxide; a metal alkoxide such as sodium methoxide, sodium ethoxide or potassium tert-butoxide; a metal amide such as sodium amide or lithium diisopropylamide; a metal hydride

The reaction is carried out in an appropriate solvent at temperatures ranging from -20°C to the boiling point of the solvent then used, preferably 0 to 150°C, for a period ranging from one minutes to ten days. As the solvent, use is made of, for example, liquid ammonia, alcohol (e.g. methanol, ethanol, propanol, iso-propanol, butyl alcohol, sec-butyl alcohol, tert-butyl alcohol, ethylene glycol, methoxyethanol or ethoxyethanol), ether (dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme or diglyme), aliphatic hydrocarbon (e.g. benzene, toluene or xylene), dimethylformamide, dimethyl sulfoxide, hexamethyl phosphoramide, sulfolane or a suitable mixture of them. Furthermore, Reformatskii reaction can be employed for causing the condensation. Referring to the conditions for Reformatskii reaction, the reagent which is usable includes, for example, zinc, magnesium, aluminum or tin, and the reaction itself can be conducted at temperatures ranging from -20°C to the boiling point of the solvent then used, preferably 0 to 150°C, for a period ranging from 30 minutes to three days. As the solvent, there may be used, for example, ether (e.g. dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme or diglyme) aliphatic hydrocarbon (e.g. pentane, hexane or heptane), aromatic hydrocarbon (e.g. benzene, toluene or xylene) or a suitable mixture of them.

The alkylation type reaction or amine exchange type reaction is conducted by allowing a compound (V) or its salt and a compound (VI) or its salt to undergo reaction, as such or in an appropriate reaction solvent, at temperatures ranging from about -10°C to the boiling point of the solvent then employed, preferably about 10 to 80°C, for a period ranging from about ten minutes to 48 hours. The ratio of the compound (VI) or its salt to be used ranges from 1 to 50 moles relative to 1 mol of the compound (V) or its salt, more preferably about 1 to 10 moles. The reaction solvent is exemplified by water, alcohol (e.g. methanol, ethanol, propanol, iso-propanol, butyl alcohol, sec-butyl alcohol, tert-butyl alcohol, ethylene glycol, methoxyethanol or ethoxyethanol), ether (e.g. diethyl ether, tetrahydrofuran, dioxane, monoglyme or diglyme), halogenated hydrocarbon (e.g. dichloromethane, chloroform or carbon tetrachloride), nitrile (e.g. acetonitrile), aliphatic hydrocarbon (e.g. pentane, hexane, heptane or octane), cyclic aliphatic hydrocarbon (e.g. cyclopentane or cyclohexane), aromatic hydrocarbon (e.g. benzene, toluene or xylene), nitromethane, pyridine, dimethylformamide, dimethyl sulfoxide, hexamethyl phosphoramide, sulfolane or a suitable mixture of them. And, it is, in some instances, desirable to carry out the reaction in the presence of a base, when necessary. Furthermore, when a phase-transfer catalyst (e.g. cetyl trimethylammonium chloride) is used in an amount of 0.01 to 0.2 equivalent, preferably about 0.02 to 0.05 equivalent, relative to the compound (V) or its salt, or the compound (VI) or its salt, the reaction can be allowed to proceed advantageously as well. In the case of the amine exchange type reaction, the reaction can in some instances be allowed to proceed under milder conditions, when a compound (V) or its salt is converted into a quaternary salt, such as the salt with methyl bromide, methyl iodide, methyl methanesulfonate, methyl benzenesulfonate or methyl p-toluenesulfonate. The above-mentioned reaction causing a Schiff base to be formed is conducted by allowing a compound (V) or its salt and a compound (VI) or its salt, as such or in an appropriate solvent, to undergo reaction at a molar ratio of (V)/(VI) = about 10 to 0.1 at temperatures ranging from -10°C to the boiling point of the solvent then used, preferably 0 to 50°C, for a period of time in the region of about ten minutes to 48 hours. In this reaction, the compound (V) or its salt and (VI) or its salt, after having their aldehyde or ketone moieties protected in the form of acetal or ketal, may be used as well. As the reaction solvent, a non-aqueous one is preferable, which is exemplified by alcohol (e.g. methanol, ethanol, propanol, iso-propanol, butyl alcohol, sec-butyl alcohol, tert-butyl alcohol, ethylene glycol, methoxyethanol or ethoxyethanol) ether (e.g. dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme or diglyme), ester (e.g. methyl acetate or ethyl acetate), halogenated hydrocarbon (e.g. dichloromethane, chloroform or carbon tetrachloride), nitrile (e.g. acetonitrile), aliphatic hydrocarbon (e.g. pentane, hexane, heptane or octane), cyclic aliphatic hydrocarbon (e.g. cyclopentane or cyclohexane), aromatic hydrocarbon (e.g. benzene, toluene or xylene), acetone, nitromethane, pyridine, dimethylformamide, dimethyl sulfoxide, hexamethyl phosphoramide, sulfolane or a suitable mixture of them. As a dehydrating agent, for example, molecular sieves, calcium chloride, magnesium sulfate, sodium sulfate or calcium sulfate is added, or the pH value of the reaction mixture is adequately adjusted with an acid (e.g. hydrochloric acid, hydrobromic acid, hydriodic acid, sulfuric acid, nitric acid or phosphoric acid), a base (e.g. a metal hydroxide such as sodium hydroxide, potassium hydroxide, lithium hydroxide or barium hydroxide; sodium methoxide, sodium ethoxide, potassium tert-butoxide, sodium carbonate, potassium carbonate, barium carbonate, calcium carbonate, sodium hydrogencarbonate, trimethylamine, triethylamine, triethanolamine or pyridine) or a buffer solution (e.g. phosphate buffer, borate buffer or acetate buffer) to thereby enhance and improve the reaction rate and yields. The reduction and reductive alkylation of the Schiff base are carried out through hydride reduction or catalytic reduction in an appropriate solvent at temperatures ranging from about -40°C to the boiling point of the solvent then employed, more preferably about 0 to 50°C. As the solvent employable, mention is made of, besides the solvents usable in the alkylation type reaction or amine exchange type reaction as described previously, acetic acid ester (e.g. methyl acetate or ethyl acetate). The catalytic reduction is carried out by using an adequate solvent at temperatures ranging from about -40°C to the boiling point of the solvent, more preferably about 0 to 50°C. As the solvent, use is made of, for example, water, alcohol (e.g. methanol, ethanol, propanol, iso-propanol, butyl alcohol sec-butyl alcohol,

tert-butyl alcohol, ethylene glycol, methoxyethanol or ethoxyethanol), acetic acid ester (e.g. methyl acetate or ethyl acetate), ether (e.g. dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme or diglyme), aromatic hydrocarbon (e.g. benzene, toluene or xylene), pyridine, dimethylformamide or a suitable mixture of them. As the catalyst for catalytic reduction, use is made of, for example, palladium, platinum, rhodium or Raney nickel. In this case, the reaction can, in some instances, be allowed to proceed advantageously by adding a small amount of acetic acid, trifluoroacetic acid, hydrochloric acid or sulfuric acid. Examples of the reagent in the hydride reduction include lithium aluminum hydride, sodium borohydride, lithium borohydride or sodium cyanoborohydride, and the amount of the reagent to be employed ranges from about equimole to 100-fold moles, usually 2-fold to 20-fold the molar quantity.

And, when the ring A is furan, thiophene, thiophen-1-oxide, thiophene-1,1-dioxide or N-substitutedpyrrole ring and -Z²- is -NH-, the said group -NH-, in some instances, undergoes ring-closure with the ring A to form a tricyclic compound (e.g. pyrrolo[3',2':4,5]pyrrolo[2,3-d]pyrimidine derivative). In this case, the tricyclic compound can be easily converted to the object dicyclic compound by processing with an acid or a base.

Second Step:

The compound (IV) or its salt as obtained in the first step can be converted into the compound (II) or its salt by allowing its ester residual group [-COOR³] to undergo the per se known deprotection reaction as employed in the production of the compound (I) or its salt.

And, the starting compound (II) or its salt can be produced also by the reaction steps as shown in the following.

In the above reaction steps, the ring A, B, R³, X, Y and Z are of the same meaning as defined above; J¹ and J² independently stand for oxygen or sulfur; R¹⁰ and R¹¹ independently stand for a hydrocarbon group; L' stands for a halogen atom (e.g. chlorine, bromine or iodine); T stands for a cyano group or a group represented by -COOR¹², -CSOR¹² or -CSSR¹² [wherein R¹² stands for a hydrocarbon residual group]; R' and R'' independently stand for hydrogen atom or a C₁₋₃ alkyl group, a C₂₋₃ alkenyl group, a C₂₋₃ alkynyl group or a cyclopropyl group as described in

detail as the substituents on the ring A. Examples of the hydrocarbon residue represented by R¹⁰, R¹¹ and R¹² include C₁₋₅ lower alkyl group (e.g. methyl, ethyl, propyl, iso-propyl, n-butyl, iso-butyl, sec-butyl, tert-butyl, n-pentyl, iso-pentyl, sec-pentyl, neo-pentyl and tert-pentyl group). These lower alkyl, benzyl and phenyl group may have one to three substituents. Such substituents include, for example, halogen atom (e.g. fluorine, chlorine, bromine, iodine), nitro group, cyano group, alkoxy group having about one to four carbon atoms (e.g. methoxy, ethoxy, propoxy, iso-propoxy, n-butoxy, iso-butoxy, sec-butoxy, tert-butoxy group), C₁₋₄ alkyl group (e.g. methyl, ethyl, propyl, isopropyl, butyl, isobutyl, sec-butyl, tert-butyl group), alkanoyl group of about one to four carbon atom (e.g. formyl, acetyl, propionyl, n-butyryl, iso-butyryl group), trifluoromethyl group and so on.

Given below is detailed description on the above reaction steps:

Third Step:

This is a step of producing the compound (VIII) or its salt by subjecting the double bond

of the compound (VII) or its salt to addition reaction to

The amount of

relative to the starting compound (VII) or its salt. The amount to be used ranges generally from about 0.5 to 4 mole equivalents, preferably about 0.8 to 1.5 mole equivalents. This reaction can be carried out in an adequate solvent at temperatures ranging from about -10°C to the boiling point of the solvent (up to about 100°C), preferably about 0 to 50°C, for about 30 minutes to 48 hours. Examples of the solvent include alcohol (e.g. methanol and ethanol), ether (e.g. dimethyl ether, diethyl ether, tetrahydrofuran, dioxane, monoglyme and diglyme), nitrile (e.g. acetonitrile), ester (e.g. ethyl acetate), halogenated hydrocarbon (e.g. dichloromethane, chloroform and carbon tetrachloride), aromatic hydrocarbon (e.g. benzene, toluene and xylene) or a suitable mixture of them. In conducting the reaction, irradiation of light or addition of an organic peroxide can, in some instances, permit the reaction to proceed more advantageously. Examples of the organic peroxide include t-butyl hydroperoxide, peracetic acid, perbenzoic acid and m-chloroperbenzoic acid. The compound (VIII) or its salt as obtained by the above procedure is of relatively high reactivity and may be isolated in this stage, while it can also be used directly in the following step without being isolated.

Fourth step:

The compound (VIII) or its salt as obtained in the third step can be led to the compound (IX) or its salt by allowing the former to react with alcohol or thiol represented by R¹¹-J²-H in an appropriate solvent at temperatures ranging from about -10°C to the boiling point (up to about 100°C) of the solvent then employed, preferably about 0 to 50°C, for about 10 minutes to 24 hours. Examples of the solvent to be employed include ether (e.g. dimethyl ether, diethyl ether,

tetrahydrofuran, dioxane, monoglyme or diglyme), nitrile (e.g. acetonitrile), ester (e.g. ethyl acetate), halogenated hydrocarbon (e.g. dichloromethane, chloroform or carbon tetrachloride), aromatic hydrocarbon (e.g. benzene, toluene or xylene) or a suitable mixture of them. Incidentally, the alcohol or thiol represented by R^{11} -J²-H may be used in excess to utilize for the solvent as well.

Fifth step:

The compound (IX) or its salt, upon reaction with a compound represented by the formula

[wherein Y is of the same meaning as defined above] or a salt thereof, is led to the compound (X) or its salt by the reaction through the cyano, ester or thioester group to cause cyclization to form the pyrimidine ring.

The acid salt of the compound (XI) or its salt includes, for example, salts with a mineral acid such as hydrochloric acid, hydrobromic acid, hydriodic acid, sulfuric acid, nitric acid, phosphoric acid or boric acid, and with an organic acid such as oxalic acid, tartaric acid, lactic acid, citric acid, acetic acid, trifluoroacetic acid, methanesulfonic acid, ethanesulfonic acid, benzenesulfonic acid or camphorsulfonic acid, while the base salt of the compound (XI-1 : Y' = hydroxyl or mercapto group) include, for example, salts formed with sodium, potassium, lithium, calcium, magnesium, aluminum, zinc, ammonium, trimethyl ammonium, triethyl ammonium, pyridinium or substituted pyridinium.

The reaction for ring-closure can, in some instances, be allowed to proceed advantageously under basic conditions. As the base, use is made of, for example, metal alkoxide such as sodium methoxide, sodium ethoxide or potassium tert-butoxide. Examples of the reaction solvent include methanol, ethanol, propanol, tert-butyl alcohol, dimethyl sulfoxide or hexamethyl phosphoramide. The reaction temperatures range from 0 to 150°C, preferably 20 to 100°C, and the reaction time ranges from one to 48 hours. Examples of the reaction solvent include methanol, ethanol, propanol, tert-butyl alcohol, dimethyl sulfoxide, hexamethyl phosphoramide or a suitable mixture of them.

Sixth step:

When necessary, the group of the formula

carbonyl group in the compound (X) or its salt is restored to a carbonyl group

(>C=O), bringing about spontaneously an intramolecular ring-closure reaction and dehydration reaction to thereby convert the compound (X) or its salt into the compound (IV) or its salt. The restoration reaction to the carbonyl group can be carried out by subjecting the compound (X) or its salt, as such or in a suitable solvent, to a per se known restoration reaction at temperatures ranging from about -10°C to the boiling point (up to about 100°C) of the solvent then employed, preferably about 0 to 50°C for about 10 minutes to 100 hours. The intramolecular ring-closure and dehydration reactions in the step of producing the compound (IV) or its salt normally allow the group X on the pyrimidine ring to condense spontaneously to the carbonyl group (>C=O) in the course of or after restoration to thereby form the ring A. In conducting the the reaction, it is also possible to allow the the reaction to proceed promptly and in an improved yield by permitting an acid catalyst to present in the reaction system. As the acid catalyst, use is made of, for example, mineral acids, organic acids or Lewis acids as described in detail referring to the aldol reaction. Also the carbonyl group (>C=O) can be reduced to a hydroxymethyl group (>CHOH), whose hydroxy moiety is converted into a leaving group L, followed by alkylation reaction with the group X in the same molecule to thereby product the compound (IV) or its salt having the ring A reduced partially. The carbonyl-group reduction, conversion of the hydroxyl group into the leaving group and the intramolecular alkylation are carried out according to per se known procedures. In addition, the compound

(II) or its salt, or (IV) or its salt can be subjected to a catalytic reduction according to a per se known, procedure to perform partial reduction to thereby to convert into the compound (II) or its salt, or the compound (IV) or its salt wherein the ring A is partially reduced. In the case of the compound (II) or its salt whose ring A is pyrrole or pyrroline ring, the compound (X) or its salt, or the compound (IV) or its salt can be subjected to a per se known alkylation or acylation reaction to thereby convert into a compound having an N-substituted pyrrole or N-substituted pyrroline ring, which falls into the scope of this invention. Furthermore, the compound of this invention whose ring A is an N-substituted pyrrole or N-substituted pyrroline ring can be produced also by conducting the above-mentioned alkylation or acylation reaction employing the compound (IV), (II) or its salt whose the ring A is an unsubstituted pyrrole or unsubstituted pyrroline ring which is described in Japanese Patent Publication Laid Open No. 167281/1990.

The starting compound (II) or its salt, whose ring A consists solely of carbon atoms, can be produced by, for example, the reaction steps as shown in the following:

[Chemical Formula 21]

In the above reaction steps, the ring A, B, R^3 , R^{12} , R' , R'' and Z are of the same meaning as defined hereinbefore, and R' , R'' and $-Z-B-COOR^3$ are to be understood to form bonding in the consecutive three positions on the cyclopentane ring.

Seventh step:

The compound (XII) or its salt as synthesized by a conventional procedure, upon treatment under heating with dicyandiamide, undergoes cyclization to form a condensed pyrimidine ring, thus yielding the compound (IV_{c1}) or its salt. In this case, the reaction temperatures ranges from 100 to 300°C, more preferably 150 to 250°C, and the suitable

reaction time ranges from one to 24 hours. When required further, dehydrogenation can be effected by following a per se known procedure with a known reagent to introduce an unsaturated bond into the ring A.

Eighth step:

Out of the two alpha-positions adjacent to the carbonyl group in the compound (XII) or its salt, the hydrogen at the alpha-position, which is not substituted with R', R'' or -Z-B-COOR³, is drawn in accordance with a conventional method to cause formation of carbanion, and an ester residue (e.g. carboxyl group which is esterified by a C₁₋₆ alkyl such as methyl, ethyl, n-propyl, iso-propyl, n-butyl, tert-butyl, or C₇₋₈ aralkyl such as benzyl) is introduced into the activated position to thereby produce the compound (XIII) or its salt.

Ninth step:

The compound (XIII) or its salt, upon treatment with the compound of the general formula (XI), reacts with its carbonyl group and ester residue to cause ring-closure and cyclization to form a condensed pyrimidine ring anew to thereby produce the compound (IV_{C2}) or its salt. As the reaction conditions, those employed in the fifth step are applied as such. When necessary furthermore, dehydrogenation can be performed in accordance with a per se known method by using a known reagent to introduce an unsaturated bond into the ring A.

The ester derivatives (IV_{C1}), (IV_{C2}) or its salt, as obtained in the 7th and 9th reaction steps, can be converted into respectively corresponding carboxylic acid derivatives by subjecting to deesterification.

In cases where B is a cycloalkenylene group or a substituted phenylene group, such group may be subjected to a catalytic reduction in any suitable one of the first to the ninth steps according to a per se known procedure to thereby convert into corresponding cycloalkylene group.

In cases Y is a hydroxyl, alkoxyl, aryloxy, 5- or 6-membered heterocyclic-oxy, mercapto, alkylthio, arylthio, 5- or 6-membered heterocyclic-thio, substituted amino, alkanoylamino, aroylamino or 5- or 6-membered heterocyclic-carbonylamino group, such group may be subjected to a conversion reaction in any suitable one of the second, sixth, seventh and ninth steps according to a per se known procedure to thereby convert into a 5- or 6-membered heterocyclic group, halogen atom, cyano group, carboxyl group, carbamoyl group, nitro group, hydroxyl group, alkoxyl group, aryloxy group, 5- or 6-membered heterocyclic-oxy group, mercapto group, alkylthio group, arylthio group, 5- or 6-membered heterocyclic-thio group, substituted amino group, alkanoylamino group, aroylamino group, 5- or 6-membered heterocyclic-carbonylamino group, alkanoyloxy group, aroyloxy group or 5- or 6-membered heterocyclic-carbonyloxy group as exemplified by Y.

In cases where the ring A and B contain a sulfur atom or -Z² is -S- (sulfur atom), the compound (I) or its salt of this invention can be converted into the compound wherein the sulfur atom of the ring A, B and -Z²- is changed into S(O)_n [n = 1 or 2] by subjecting the compound (I) or its salt to oxidation directly or in an optional one of the feasible steps. The reaction for oxidation can be carried out in an appropriate solvent, usually in the presence of an oxidizing agent of 0.3 to 3.0 equivalents relative to the compound to be oxidized, preferably 0.5 to 2.5 equivalents at temperatures ranging from -10 to +100°C, preferably 0 to +50°C for 10 minutes to 48 hours, preferably 30 minutes to 24 hours. Preferred examples of the oxidizing agent to be used for the reaction include peracids (e.g. sodium metaperiodate, hydrogen peroxide, peracetic acid, perbenzoic acid and m-chloroperbenzoic acid). Examples of the reaction solvent to be employed include water, acetic acid ketone (e.g. acetone and ethyl methyl ketone), ether (e.g. dimethyl ether, diethyl ether, dioxane, monoglyme and diglyme), halogenated hydrocarbon (e.g. dichloromethane, chloroform and carbon tetrachloride), aliphatic hydrocarbon (e.g. pentane, hexane, heptane and octane), cyclic aliphatic hydrocarbon (e.g. cyclopentane and cyclohexane), aromatic hydrocarbon (e.g. benzene, toluene and xylene), acetonitrile or a suitable mixture of them.

Furthermore, the amino, hydroxyl or mercapto group as represented by X in the compounds (I), (II), (IV) or its salt can be converted into one another, as the case may be, according to a known reaction for substituent replacement on the pyrimidine ring [Supplement volume of "Tanpakushitsu/Kakusan/Kouso (Proteins/Nucleic Acids/Enzymes)", Chemical Synthesis of Nucleic Acid, Published by Kyoritsu Publishing Co. of Japan (1968)].

The method of the starting compound (III) or its salt will be described hereinafter. The starting compound (III) or its salt can be produced by, for example, the reaction steps as shown below:

10th step

11th step

12th step

In the above reaction scheme, W, R¹, R² and p are of the same meaning as defined hereinbefore, Q and V are group capable of forming the amido-linkage W by bonding to each other. R¹³ stands for amino group and R¹⁴ stands for carboxyl group.

Tenth step:

This is the method of producing the compound (IV) or its salt after protecting the amino group and carboxyl group of the alpha-amino acid (VIV) with a per se known protective group. As the protecting group of amino group, use is made of, for example, salts with an acid (e.g. hydrochloride, sulfate, nitrate, phosphate, acetate, trifluoroacetate, p-toluenesulfonate and methanesulfonate), amides (e.g. formyl, acetyl, chloroacetyl, trichloroacetyl, trifluoroacetyl, pivaloyl, benzoyl, p-nitrobenzoyl and p-methoxybenzoyl), imides (e.g. phthaloyl and dithiosuccinoyl), carbamates (e.g. methoxycarbonyl, ethoxycarbonyl, isobutyroxycarbonyl, tert-butoxycarbonyl, cyclohexyloxycarbonyl, benzyloxycarbonyl, p-nitrobenzyloxycarbonyl and phenoxycarbonyl), benzyl group (e.g. benzyl, o-nitrobenzyl, diphenyl methyl and trityl) and silyl group (e.g. trimethyl silyl, triethyl silyl, dimethyl-tert-butyl silyl, diphenyl-tert-butyl silyl and diisopropyl-

methyl silyl), while, as the protecting group of carboxylic group, use is made of, for example, esters (e.g. methyl, ethyl, propyl, isopropyl, butyl, sec-butyl, isobutyl, tert-butyl, benzyl, p-nitrobenzyl and phenyl), amides (e.g. N,N-dimethyl amide, pyrrolidiny amide and piperaziny amide), silyl esters (e.g. trimethyl silyl, triethyl silyl, dimethyl-tert-butyl silyl, diphenyl-tert-butyl silyl and diisopropylmethyl silyl), metal salts (e.g. sodium, lithium, potassium, calcium, barium, magnesium, copper and silver) and ammonium salts. This reaction can be carried out in an appropriate solvent at temperatures ranging from about 20°C to the boiling point of the solvent, preferably 0 to 80°C, for about 10 minutes to 48 hours. Examples of the solvent to be used for the reaction include water, alcohol (e.g. methanol, ethanol and t-butanol), ether (e.g. diethyl ether, tetrahydrofuran, dioxane, monoglyme and diglyme), nitrile (e.g. acetonitrile), ester (e.g. ethyl acetate), halogenated hydrocarbon (e.g. dichloromethane, chloroform and carbon tetrachloride), aromatic hydrocarbon (e.g. benzene, toluene and xylene), pyridine, dimethylformamide, dimethyl sulfoxide or a mixture of them.

Eleventh step:

For the formation of amido-linkage of W, a known reaction is employed. In the compounds (XV), (XVI) or its salt, when Q is NH₂, V is carboxyl group or its reactive derivative, while, when Q is carboxyl group or its reactive derivative, V is NH₂. The reactive derivatives at the carboxyl group or its reactive derivatives are of the same meaning as those shown by the compound (II) or its salt. Especially, when introduction of the phthaloyl group is intended, it is advantageous to use the Nefken's reagent [Nature, 185, 309, (1960)].

Twelfth step:

The compound (XVII) or its salt obtained by the 11th step can be converted into the compound (III) or its salt by subjecting amino group thereof to a deprotection reaction according to a per se known procedure described in T. W. Green, Protective Group in Organic Synthesis, John Wiley & Sons, New York (1981). In the case where both the amino group and the carboxyl group were protected simultaneously by using the formation of copper chelate, the compound (XVII) or its salt can be converted into the compound (III) or its salt by subjecting the carboxyl group to esterification after removal of the copper by the aid of, for example, hydrogen sulfide, 6N HCl, ethylenediamine tetraacetate (EDTA) under acid conditions.

Incidentally, the reaction for formation of the amido linkage W can be conducted for the compound (XX) or its salt as well.

In the above formulae, X, Y, the ring A, Z, B, R¹, p, W, R², Q and V are of the same meaning as defined above. R¹⁵ is a protecting group of the functional group Q, and, when Q is amino group, R¹⁵ is, for example, carbamate (e.g. methoxycarbonyl, ethoxycarbonyl, propyloxycarbonyl, isopropyloxycarbonyl, tert-butoxycarbonyl, benzyloxycarbonyl or 9-fluorenylmethoxycarbonyl), amido (e.g. chloroacetyl), or silyl group (e.g. trimethylsilyl, triethylsilyl, dimethyl-tert-butylsilyl or diphenyl-tert-butylsilyl); while, when Q is carboxyl group, R¹⁵ is, for example, ester (tert-butyl, benzyl, p-nitrobenzyl or 2-trimethylsilylethyl).

Thirteenth step:

The compound (XIX) or its salt can be produced by subjecting the compound (III) or its salt and the compound (XVIII) or its salt to substantially the same condensation as in the case of production of the compound (I) or its salt.

Fourteenth step:

The compound (XIX) or its salt obtained in the 13th step is subjected to the reaction for deprotection of the functional group Q, in substantially the same manner as in twelfth step to thereby produce the compound (XX) or its salt.

Fifteenth step:

The compound (XX) or its salt obtained in the 14th step is subjected to a per se known amido-forming reaction to allow the amido-bondage W through Q and V to thereby produce the compound (I) or its salt.

Incidentally stating, the reactions, reagents and reaction conditions as well as the protective group as employed upon necessity, which are carried out or employed in the 1st step through 15th step or in the step of producing the starting compound, are conducted by the known methods described in detail in the following literature references. [J. F. M. McOmie, "Protective Groups in Organic Chemistry" Plenum Press, London and New York (1973), [Pine, Hendrickson and Hammond, "Organic Chemistry" (4th edition), [I] to [II], Hirokawa Shoten of Japan] and [M. Fieser and L. Fieser, "Reagent for Organic Synthesis" Vol. 1 to 13, Wiley-Interscience, New York, London, Sydney and Toronto (1969-1988)].

Each of the intermediates of the compounds of this invention as well as the compound (I) or its salt of this invention produced by the methods described in the foregoing can be isolated from the reaction mixture by conventional separating means, for example, concentration, solvent extraction, chromatography and recrystallization. The resultant mixed can be used as materials in next step without separating.

Examples of salts of the compounds (I), (II), (III), (IV), (IV_{c1}), (IV_{c2}), (V), (VI), (VII), (VIII), (IX), (X), (XII), (XIII), (XIV), (XV), (XVI), (XVII), (XVIII), (XIX) and (XX) obtainable by the above production method include the salts formed with bases such as alkali metals, alkaline earth metals, non-toxic metals, ammonium or substituted ammonium, more specifically, salts with sodium, potassium, lithium, calcium, magnesium, aluminum, zinc, ammonium, trimethylammonium, triethylammonium, triethanolammonium, pyridinium and substituted pyridinium, or salts formed with acids such as mineral acids, such as hydrochloric acid, sulfuric acid, nitric acid, phosphoric acid and boric acid, and salts formed with organic acids, such as oxalic acid, tartaric acid, acetic acid, trifluoroacetic acid, methanesulfonic acid, benzenesulfonic acid, p-toluenesulfonic acid and camphorsulfonic acid.

Incidentally stating, the compounds (V), (VI), (VII), (X), (XI), (XII), (XIV), (XVI), (XVIII) or its salt can be easily produced by conventional methods or per se conventional methods.

Moreover, the compound (I) or its salt of this invention can be used in safety and with lower toxicity as a agent for antirheumatism.

Given below is description on the experimental results showing pharmacological effects of the compound (I) or its salt in the present invention.

Cell-proliferation inhibitory effects (IC₅₀) of the compound obtained in the first of Example 5 described hereafter against A549 cells were determined by the following method.

Each hole of a 96-hole microwell plate was inoculated with 1 ml of human lung cancer A549 cells (5 x 10³/ml) prepared by a conventional method. The plate was incubated statically for 24 hours at 37°C in 5% CO₂, to which was added a 10% MEM (Nissui Seiyaku, JAPAN) solution of the said compound, and the incubation was continued for further 5 days under the same conditions as above. The culture solution was removed with a micropipette, then 0.1 ml each of a fresh 10% MEM solution (1.0 mg/ml) of MTT (Dojin Kagaku, JAPAN) was added to holes and the plate was incubated at 37°C for 24 hours. Then 0.1 ml each of a 10% SDS (Wako Pure Chemicals Industries, Ltd., JAPAN) was added to holes and the plate was incubated at 37°C for further 24 hours. The absorbance at the wavelength of 590 nm was determined. The concentration of the drug required for decreasing the cell number in the control group by 50% was assumed to be IC₅₀ value of the compound. The results were shown in Table 1.

As is apparent from results of the above experiment, the compound (I) or its salt show excellent inhibitory effects against cell proliferation. And, the compound (I) or its salt of this invention or their salts are less toxic and have remarkable anti-tumor activities. Therefore, preparations containing a compound (I) or its salt can be used as antitumor agent aiming at the therapy of tumors of warm-blooded animals, especially mammals (e.g. mouse, rat, cat, dog and rabbit).

The compounds (I) or its salt, when intended to use as an antitumor agent or antirheumatism, can be administered orally or non-orally, as such or after being processed into such dosage forms as powder, granule, tablet, capsule, suppository and injectable solution by means of conventional procedures with use of pharmaceutically acceptable carriers, excipients, diluents and the like. Their dosage amount varies with the species of subject animals, type of diseases, severity of symptoms, kind of compounds or route of administration, and their daily dose for the above warm-blooded animals is about 2.0 to 200 mg/kg body weight, preferably 4.0 to 80 mg/kg body weight in terms of the compound of this invention in the case of oral administration, while the daily dose ranges from about 1.0 to 100, preferably 5-100 mg/kg in the case of non-oral administration. The method of administration for injectable solutions includes, for example, intramuscular injection, intraperitoneal injection, subcutaneous injection and intravenous injection.

The above-mentioned procedures of processing into pharmaceutical preparations are conducted in accordance with per se known methods. In manufacturing the above-mentioned oral preparations, for example, tablets, a binder (e.g. hydroxypropyl cellulose, hydroxypropyl methylcellulose or macrogol), a disintegrating agent (e.g. starch and carboxymethylcellulose calcium) and a lubricant (e.g. magnesium stearate and talc), among others, can be suitably incorporated. And, in manufacturing non-oral preparations; for example, injectable solutions, an isotonicizing agent (e.g. glucose, D-sorbitol, D-mannitol and sodium chloride), a preservative (e.g. benzyl alcohol, chlorobutanol, methyl p-oxybenzoate and propyl p-oxybenzoate), and a buffer solution (e.g. phosphate buffer and sodium acetate buffer), among others, can be suitably incorporated.

With reference to a specific example of the manufacture of tablets, use is made of, for example, about 1.0 to 50 mg of a compound of this invention, 100 to 500 mg of lactose, about 50 to 100 mg of corn starch and about 5 to 20 mg of hydroxypropyl cellulose, being weighed out for use in the manufacture of one tablet, and they are mixed and tableted to give a tablet weighing about 100 to 500 mg and measuring about 3 to 10 mm in diameter. And, the resulting tablet can furthermore be processed into an enteric coated tablet by providing coating with use of an about 5 to 10% solution of hydroxypropyl methylcellulose phthalate (about 10 to 20 mg) and castor oil (about 0.5 to 2.0 mg) in acetone-ethanol mixture. Referring to a specific example of producing injectable solutions, for example, about 2.0 to 50 mg per ampoule of sodium salt of the compound (I), (1) is dissolved in about 2 ml of physiological aqueous saline solution, and the solution is filled into an ampoule, followed by fusion and heat sterilization at about 110°C for about 30 minutes, or (2) is dissolved in a solution of about 10 to 40 mg of mannitol or sorbitol in about 2 ml of sterilized distilled water is filled into an ampoule, followed by lyophilization and fusion to thereby prepare an injectable solution. On the occasion of using the lyophilized compound, the said ampoule is opened, and a physiological aqueous saline solution is poured into the ampoule to make a solution having a concentration of, for example 1.0 to 50 mg/ml of the compound. The solution can be used as an injectable preparation subcutaneously, intravenously or intramuscularly.

The present invention is illustrated in further detail by the following Reference Examples and Examples, which are only examples and do not limit the present invention. Modification within the scope of the present invention are permissible.

In the present specification, room temperature means 10-35°C.

Production of N(α)-[4-[3-(2,4-diamino-7H-pyrrolo[2,3-d]pyrimidin-5-yl)propyl]benzoyl]-N-(3-borophenyl)-L-glutamine

To a methanol/tetrahydrofuran (2:1 ; 15 ml) solution of methyl N(α)-[4-[3-(2,4-diamino-7H-pyrrolo[2,3-d]pyrimidin-5-yl)propyl]benzoyl]-N-(3-borophenyl)-L-glutamate (1 g) was added a 1N aqueous solution (6 ml) of sodium hydroxide (6 ml), and the mixture was stirred for 5 hours at room temperature. The reaction mixture was concentrated under reduced pressure. The concentrate was dissolved in water, whose pH was adjusted to 4 with 1N hydrochloric acid. Resulting precipitates were collected by filtration, washed with water, then dried under reduced pressure to afford the subject compound (839 mg; yield 86%).
